## 1 STABILITY

## 1.1 Second order System

1.1. Consider the following second order system with the transfer function

$$G(s) = \frac{1}{1 + 2s + s^2} \tag{1.1.1}$$

Is the system stable?

**Solution:** 

$$G(s) = \frac{1}{1 + 2s + s^2}$$
 (1.1.2)

From given expression of G(s),both poles of G(s) are at (-1,0) which is on the left half of s-plane, therefore we can conclude that the system is stable.

1.2. Find and sketch the step response c(t) of the system.

**Solution:** For step-response, we take input as unit-step function u(t)

$$C(s) = R(s).G(s) = \left[\frac{1}{s}\right] \left[\frac{1}{1+2s+s^2}\right]$$
(1.2.1)

$$C(s) = \frac{1}{s(1+s)^2}$$
 (1.2.2)

Using Partial Fractions,

$$C(s) = \frac{1}{s} - \frac{1}{(1+s)} - \frac{1}{(1+s)^2}$$
 (1.2.3)

Therefore;

$$c(t) = L^{-1} \left[ \frac{1}{s} \right] - L^{-1} \left[ \frac{1}{1+s} \right] - L^{-1} \left[ \frac{1}{(1+s)^2} \right]$$
(1.2.4)

Using the Known inverse transforms:

$$c(t) = (1 - e^{-t} - te^{-t}).u(t)$$
 (1.2.5)

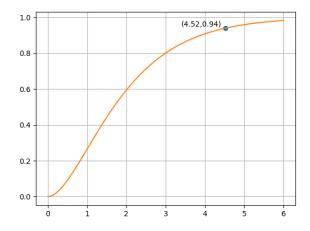

Fig. 1.2

import numpy as np import matplotlib.pyplot as plt

x = np.linspace(0,6,1000) y = 1-(np.exp(-x))-(x\*np.exp(-x)) plt.plot(4.52218,0.94,'o') plt.text(3.4,0.95,'(4.52,0.94)') plt.grid() plt.plot(x,y) plt.show()

1.3. Find the steady state response of the system. **Solution:** To know the steady response value of c(t), we calculate

$$\lim_{t \to \infty} c(t) = (1 + 0 + 0).(1) = 1 \tag{1.3.1}$$

1.4. Find the time system output c(t) to reach 94% of its steady state value.

**Solution:** Now, 94% of 1 is 0.94, so we should now solve for a positive t such that

$$(1 - e^{-t} - te^{-t}) = 0.94 (1.4.1)$$

import numpy as np import matplotlib.pyplot as plt

$$t = 0$$

$$c = 0$$

$$y = 0$$

# defining a function whose solution of f=0 will give us the value of t for 94% of output

def s(a):  

$$v = 0.06 - \text{np.exp}(-a) - a*\text{np.exp}(-a)$$
a)
return v

#loop starts at t = 0, checks wether function is +ve, if not, then increases t by 0.001 while c == 0:

$$y = s(t)$$
  
if  $y < 0$ :  
 $c = 0$   
 $t = t+0.001$ 

else:

c = 1

#approx. the curve as a straight line, we find the crossing point by weighted mean of the two succesive values

$$\begin{array}{l}
 t1 = ((t-0.001)*(-s(t-0.001)) + t*s(t))/(-s(t-0.001) + s(t))
 \end{array}$$

print(t1)

$$t = 4.5228 \tag{1.4.2}$$
